

Remote Monitoring MIB Extensions for  
Differentiated Services

Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes managed objects used for monitoring Differentiated Services (DS) Codepoint usage in packets which contain a DS field, utilizing the monitoring framework defined in the RMON-2 (Remote Network Monitoring Management Version 2) MIB.

## 1. The SNMP Network Management Framework

The SNMP Management Framework presently consists of five major components:

- o An overall architecture, described in RFC 2571 [RFC2571].
- o Mechanisms for describing and naming objects and events for the purpose of management. The first version of this Structure of Management Information (SMI) is called SMIv1 and is described in STD 16, RFC 1155 [RFC1155], STD 16, RFC 1212 [RFC1212] and RFC 1215 [RFC1215]. The second version, called SMIv2, is described in STD 58, RFC 2578 [RFC2578], RFC 2579 [RFC2579] and RFC 2580 [RFC2580].
- o Message protocols for transferring management information. The first version of the SNMP message protocol is called SNMPv1 and is described in STD 15, RFC 1157 [RFC1157]. A second version of the SNMP message protocol, which is not an Internet standards track protocol, is called SNMPv2c and is described in RFC 1901 [RFC1901] and RFC 1906 [RFC1906]. The third version of the message protocol is called SNMPv3 and is described in RFC 1906 [RFC1906], RFC 2572 [RFC2572] and RFC 2574 [RFC2574].
- o Protocol operations for accessing management information. The first set of protocol operations and associated PDU formats is described in STD 15, RFC 1157 [RFC1157]. A second set of protocol operations and associated PDU formats is described in RFC 1905 [RFC1905].

- o A set of fundamental applications described in RFC 2573 [RFC2573] and the view-based access control mechanism described in RFC 2575 [RFC2575].

A more detailed introduction to the current SNMP Management Framework can be found in RFC 2570 [RFC2570].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the mechanisms defined in the SMI.

This memo specifies a MIB module that is compliant to the SMIV2. A MIB conforming to the SMIV1 can be produced through the appropriate translations. The resulting translated MIB must be semantically equivalent, except where objects or events are omitted because no translation is possible (use of Counter64). Some machine readable information in SMIV2 will be converted into textual descriptions in SMIV1 during the translation process. However, this loss of machine readable information is not considered to change the semantics of the MIB.

## 2. Overview

There is a need for a standardized way of monitoring the network traffic usage of Differentiated Services (DS) [RFC2474] codepoint values. Each DS codepoint (DSCP) value may be given a different treatment by a forwarding device, and this affects which packets get dropped or delayed during periods of network congestion.

The IETF DIFFSERV working group has redefined the semantics of the Type of Service (TOS) octet in the IP header, which is now called the 'DS field'. The 6-bit Codepoint (DSCP) portion is contained in the DS field, which provides for 64 different packet treatments for the implementation of differentiated network services.

By polling DSCP usage counters, an NMS can determine the network throughput for traffic associated with different DSCPs. This data can then be analyzed in order to 'tune' DSCP 'allocations' within a network, based on the Quality of Service (QoS) policies for that network.

Remote monitoring agents are typically implemented as independent software (and sometimes hardware) components, called 'RMON probes'. Note that DSMON-capable RMON probes simply collect and aggregate statistics, based on criteria (which includes the DSCP value) that can be determined by inspecting the contents of monitored packets and do not in any way monitor any aspect of a DS forwarding device's internal statistics.

## 2.1. Terms

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14, RFC 2119. [RFC2119]

This document uses some terms that need introduction:

### DataSource

A source of data for monitoring purposes. This term is used exactly as defined in the RMON-2 MIB [RFC2021].

### protocol

A specific protocol encapsulation, as identified for monitoring purposes. This term is used exactly as defined in the RMON Protocol Identifiers document [RFC2074].

### Counter Aggregation Group

A group of statistical counters that are being combined in the agent to produce one aggregated counter. Refer to sections 3.1 and 3.2.1 for details on counter aggregation groups.

### Counter Aggregation Profile

Also called 'profile'; A complete set of counter aggregation group mappings for DSCP values (i.e., 64 mappings, for each DSCP values 0 to 63), which are applied to all monitored packets on a particular data source and/or DSMON collection. Refer to sections 3.1 and 3.2.1 for details on counter aggregation profiles.

### High Capacity Monitoring

The generic capability to collect and store statistics with an internal range of 64 bits (e.g., Counter64). This term does not refer to implementation of the High Capacity RMON MIB [RFC3273].

## 2.2. Relationship to Differentiated Services

The DSMON MIB is a product of the RMONMIB WG, not the DIFFSERV WG, and it focuses on extending several existing RMON mechanisms to support additional packet classification, based on DSCP values observed in monitored packets. This document assumes the reader is familiar with the DS Architecture [RFC2475].

It is expected that complex management applications will use the counters in this MIB to help analyze DS-related throughput. It is expected that other metrics, such as delay and jitter, will also be analyzed, but support for other metrics is outside the scope of this document.

### 2.3. Relationship to the Remote Monitoring MIBs

This MIB is intended to be implemented in Remote Monitoring (RMON) probes, which support the RMON-2 MIB [RFC2021]. Such probes may be stand-alone devices, or may be co-located with other networking devices (e.g., ethernet switches and repeaters).

The DSMON functions are intended to be implemented in conjunction with the associated RMON functions, but the MIB is independent of all other RMON data tables.

Several concepts and even MIB objects from the RMON MIBs are used in the DSMON MIB:

#### Protocol Directory

The RMON-2 MIB [RFC2021] defines the protocolDirTable, which is a directory of all the protocols that the RMON-2 agent is capable of decoding and counting. The DSMON MIB utilizes this directory to identify the protocols detected in monitored packets. The protocolDirLocalIndex MIB object is used to identify protocol encapsulations in all DSMON data tables which classify and aggregate by protocol type in some manner. Note that the protocolDirTable is used for protocol identification only, independent of DSCP classification.

#### TimeFilter

The RMON-2 TimeFilter textual convention provides a mechanism to retrieve only rows which have been created or modified since the last polling interval (for a particular NMS). The DSMON MIB uses this textual convention in the large data tables, in order to minimize polling impact.

#### Zero-Based Counters

Since counters are instantiated by management action, as in the RMON MIBs, the DSMON MIB uses zero-based counters in all data collection tables. Specifically, the ZeroBasedCounter32 textual convention from the RMON-2 MIB [RFC2021] and the ZeroBasedCounter64 textual convention (defined in the HCNM-TC MIB [RFC2856]) are used to define counter objects in this MIB.

#### High Capacity Counters

The DSMON MIB uses the 'SNMPv1 coexistence' strategy adopted by the RMONMIB WG. That is, where a 64-bit counter is provided, a 32-bit version of the counter, and a 32-bit overflow counter are also provided.

TopN Reports

The DSMON MIB uses the same TopN reporting MIB structure as the RMON-2 MIB [RFC2021]. TopN reporting can greatly reduce the polling overhead required to analyze DSCP usage patterns.

Some DESCRIPTION clauses for DSMON objects are very similar to those for existing RMON-2 or HC-RMON objects. This is intentional, since the semantics of the DSMON features are designed to be as close to existing RMON feature as possible, to allow developers and users some level of 'MIB re-use'.

3. MIB Structure

Figure 1: DSMON MIB Functional Structure

The DSMON MIB can be divided into three functional components:

- DSMON Capabilities  
Describes which DSMON object groups are supported by the agent on at least one data source.
- Counter Aggregation Control  
Controls how individual DIFFSERV codepoint counters are aggregated in DSMON data collections.
- Data Collection  
Controls how individual statistical collections are maintained by the agent and reported to management applications. The individual boxes within the Data Collection box represent the DSMON data collections (described in section 3.2):
  - Data Source Statistics
  - Protocol Statistics
  - Protocol Statistics TopN Reporting
  - Network Protocol Host Statistics
  - Network Protocol Host Statistics TopN Reporting
  - Application Protocol Matrix Statistics
  - Application Protocol Matrix Statistics TopN Reporting

### 3.1. DSCP Counter Aggregation

A mechanism to configure the agent to internally aggregate counters is provided, based on DSCP values. This is desirable for several reasons:

- agent data reduction  
An agent implementation can potentially reduce the number of counters maintained for a given DSMON collection.
- agent data collection limitations  
Some implementation strategies might provide for a limited number of high-speed (e.g., hardware-based) counters for either single or aggregated codepoints.
- application data retrieval reduction  
Applications that would otherwise aggregate counters for individual codepoints can move that function to the agent in order to reduce the polling overhead on the application, the network, and the agent device.
- some unused codepoints at this time  
Various DSCP values may be expected to remain unused on a given network, and may be aggregated for counting purposes.

- some DSCP values are mapped to the same packet treatment  
A network administrator may align the counter aggregation configuration of the monitoring device with the DS configuration, and aggregate statistics for DSCP values which are expected to receive the same treatment by the forwarding devices.

### 3.1.1. Counter Aggregation Configuration

The configuration of DSCP counter to counter aggregation group mappings is managed in a global manner, so that these settings can be shared across several DSMON collections and/or data sources. One complete set of DSCP counter mappings is called a counter aggregation profile. The DSMON control tables are very similar to existing RMON-2 control tables, except they contain an extra parameter to identify the counter aggregation profile the agent should use for the collection.

The appropriate granularity for counter aggregation profile assignment may be the data source, but in order to reduce MIB complexity (by avoiding an extra layer of tables), an instance of the counter aggregation profile parameter exists for each collection. An agent MAY choose to restrict configurations such that all DSMON data collections for the same data source must use the same counter aggregation profile.

The DSMON MIB supports the configuration of an arbitrary number of counter aggregation profiles. There is a top-level counter aggregation control table, which contains one entry for each counter aggregation profile. A subordinate counter aggregation profile table provides information about each DSCP counter to counter aggregation group mapping in each profile. An auxiliary counter aggregation group table also provides descriptive information about each counter aggregation group in each profile. Refer to section 3.2.1 for details on these MIB objects.

### 3.2. MIB Group Overview

The DSMON MIB contains six groups of MIB objects:

- dsmonAggregateControl group  
Controls the configuration of counter aggregation groups for the purpose of reducing the total number of counters maintained by the agent.
- dsmonStatsObjects group  
Report per counter aggregation group distribution statistics for a particular RMON dataSource.

- dsmonPdistObjects group  
Report per counter aggregation group distribution statistics for each application protocol detected on a particular RMON dataSource.
- dsmonHostObjects group  
Report host address distribution statistics for each counter aggregation group, detected on a particular RMON dataSource.
- dsmonCapsObjects group  
Report the static DSMON MIB functional capabilities of the agent implementation.
- dsmonMatrixObjects group  
Report host address pair distribution statistics for each counter aggregation group, detected on a particular RMON dataSource.

### 3.2.1. DSCP Counter Aggregation Control Group

This group contains 4 scalar objects and three tables, and is used by a management station to configure counter aggregation profiles.

The dsmonMaxAggGroups scalar is a read-only integer which indicates the maximum number of counter aggregation groups that the agent will allow to be configured into a single aggregation profile. This value SHOULD be equal to 64 (the number of codepoints), but an agent MAY limit the number of counter aggregation groups because of resource limitations (e.g., small number of hardware-based counters). At least one counter aggregation profile containing at least two counter aggregation groups SHOULD be supported by the agent. (Note that classifying all DSCP counters into the same statistical 'bucket' may yield a redundant data collection, which can be achieved more easily with an HC-RMON or RMON-2 collection instead.)

The dsmonAggControlLocked scalar is used as a top level switch, controlling most write access to the dsmonAggControlTable, dsmonAggProfileTable, and dsmonAggGroupTable. (The dsmonAggControlOwner object is the only exception.) All active DSMON collection data is deleted, and collection suspended, while this object is equal to 'false', since the meaning of one or more counter aggregation control tables may change when it is set back to 'true'.

The dsmonAggControlChanges counter and dsmonAggControlLastChangeTime timestamp can be used by a management station to detect that the codepoint to counter aggregation group mappings may have changed between polls.

The dsmonAggControlTable is a read-create table which contains one entry for each counter aggregation profile configured on the agent. Each entry is identified by a dsmonAggControlIndex value, which is also used as the major index into the dsmonAggProfileTable and dsmonAggGroupTable. The DSMON control tables with DataSource objects select a counter aggregation profile by referencing this index value.

The dsmonAggProfileTable is a read-write table which contains 64 rows for each associated entry in the dsmonAggControlTable, which MUST be indexed from 0 to 63. The agent creates this set of 64 instances when the associated dsmonAggControlEntry is activated, and deletes them when that dsmonAggControlEntry is deactivated. Each of the 64 rows represents a conceptual DSCP counter, identified by the same dsmonAggProfileDSCP value, and contains the DSCP counter to counter aggregation group mapping for that DSCP counter, in the indicated profile. The agent SHOULD use the value zero as the initial counter aggregation group assignment for each entry in this table.

The dsmonAggGroupTable contains an administratively assigned descriptive label for each configured counter aggregation group. This table is not required to be fully configured in order for data collection to occur, since collections are identified by the agent with integer indices. It is provided to allow the agent to store a descriptive string for each configured counter aggregation group. There is no attempt made to convey any real semantics for each counter aggregation group. A management station MAY choose not to configure entries in this table.

### 3.2.2. DS Statistics Group

This group contains two tables, the dsmonStatsControlTable and the dsmonStatsTable, and supports counter aggregation group distribution statistics for half and full-duplex, low and high speed interfaces. Packet and octets distributions are maintained in the dsmonStatsTable for each active control row in the dsmonStatsControlTable.

This group provides the lowest statistics granularity in the DSMON MIB. It is expected that a management application will analyze certain DS deployment or performance problems by first examining the counter aggregation group distribution for an entire data source with this group.

### 3.2.3. DS Protocol Distribution Group

This group contains two tables for statistics collection, (dsmonPdistCtlTable and dsmonPdistStatsTable), and two tables for a 'Top N' reporting function for the collected statistics (dsmonPdistTopNCtlTable and dsmonPdistTopNTable).

The dsmonPdistCtlTable and dsmonPdistStatsTable tables provide counter aggregation group distribution statistics for each selected protocol encapsulation in packets monitored on a particular dataSource. Packet and octets distributions (per counter aggregation group per protocol) are maintained in the dsmonPdistStatsTable for each active control row in the dsmonPdistCtlTable.

Due to the potentially large number of entries, the DS Protocol Distribution is different from the RMON-2 protocol distribution group in several ways:

- maximum desired entries parameter added to the control table
- inserts and deletes counters added to the control table
- support for LRU garbage collection in the dsmonPdistStatsTable
- TimeFilter index added to the dsmonPdistStatsTable
- the selection of protocols is not configurable. Rather than select individual protocols to monitor, (e.g., via a 'supportedOn/Off' extension to the protocolDirTable [RFC 2021]), a simplified configuration mechanism is provided. Since DSCP usage statistics are most interesting at the application layer, the dsmonPdistStatsTable is 'hardwired' to select only application layer (i.e., 'terminal') protocols for statistical analysis.

The TopN feature requires two additional tables: the dsmonPdistTopNCtlTable and the dsmonPdistTopNTable, and supports periodic usage reporting for the statistics maintained in the dsmonPdistStatsTable. This feature allows for simple periodic retrieval of the most used application/counter aggregation group combinations.

#### 3.2.4. DS Host Distribution Group

This group contains two tables for statistics collection, (dsmonHostCtlTable and dsmonHostTable), and two tables for a 'Top N' reporting function for the collected statistics (dsmonHostTopNCtlTable and dsmonHostTopNTable).

The dsmonHostCtlTable and dsmonHostTables provide host distribution statistics for each counter aggregation group detected in packets monitored on a particular dataSource. The DSMON Host collection is similar to the RMON-2 network layer host collection (nlHostTable). There is no DSMON application host table defined at this time.

It is expected that a management application will analyze certain DS deployment or performance problems by first determining the high priority DSCP values to examine (beyond the scope of this document) and then examining the dsmonHostTable or dsmonHostTopNTable statistics to determine which hosts are using the selected counter aggregation groups.

Packet and octets distributions (in and out, per counter aggregation group per host) are maintained in the dsmonHostTable for each active control row in the dsmonHostCtlTable.

The DS Host Distribution is different from the RMON-2 network layer host group in two ways:

- the protocolDirLocalIndex in the INDEX clause MUST identify a network protocol encapsulation which contains a DS field (e.g., IPv4 or IPv6). If a protocol encapsulation with multiple network layers is specified, then associated entries in this table refer to the innermost network protocol layer.
- the dsmonHostCtlTable supports limited IPv4 and IPv6 prefix aggregation by allowing the number of 'monitored address bits' in each address to be configured for each collection. The agent will zero out the selected number of rightmost address bits for counting purposes. This configuration parameter can dramatically reduce the number of entries which must be maintained by the agent, which should reduce CPU and memory resource requirements on the agent, and reduce polling overhead on the network and the management station. However, only one mask can be configured for each address type, rather than multiple different length masks for each address type, based on prefix value.

The TopN feature requires two additional tables: the dsmonHostTopNCtlTable and the dsmonHostTopNTable, and supports periodic usage reporting for the statistics maintained in the dsmonHostTable. This feature allows for simple periodic retrieval of the most used IP-host/DSCP combinations.

### 3.2.5. DSMON Capabilities Group

This group contains a single read-only scalar object, dsmonCapabilities, which provides an indication of the MIB groups within this MIB that the agent supports.

### 3.2.6. DS Matrix Distribution Group

This group contains three tables for statistics collection, (dsmonMatrixCtlTable, dsmonMatrixSDTable, and dsmonMatrixDSTable), and two tables for a 'Top N' reporting function for the collected statistics (dsmonMatrixTopNctlTable and dsmonMatrixTopNTable).

The dsmonMatrixCtlTable, dsmonMatrixSDTable, and dsmonMatrixDSTable provide host-pair distribution statistics for each counter aggregation group detected in packets monitored on a particular dataSource. The DSMON Matrix collection is similar to the RMON-2 application layer matrix collection (alMatrixSDTable and alMatrixDSTable). There is no DSMON network layer matrix table defined at this time.

It is expected that a management application will analyze certain DS deployment or performance problems by first determining the high priority DSCP values to examine (beyond the scope of this document) and then examining the dsmonMatrixSDTable, dsmonMatrixDSTable, and/or dsmonMatrixTopNTable statistics to determine which host-pairs are using the selected counter aggregation groups.

Packet and octets distributions (source to destination, per counter aggregation group per host-pair) are maintained in the dsmonMatrixSDTable and dsmonMatrixDSTable for each active control row in the dsmonMatrixCtlTable.

The TopN feature requires two additional tables: the dsmonMatrixTopNctlTable and the dsmonMatrixTopNTable, and supports periodic usage reporting for the statistics maintained in the dsmonMatrixSDTable. This feature allows for simple periodic retrieval of the most used IP-host-pair/DSCP combinations.

### 3.3. RMON vs. DSMON Indexing Structure

The DSMON-MIB control and data tables are very similar in structure and look-and-feel to existing RMON-2 and HC-RMON control tables for the comparable feature, in order to maintain consistent agent behavior and functionality across RMON MIBs. The DSMON data tables are indexed as closely as possible to the comparable RMON-2 or HC-RMON tables, with the addition of an index component for DSCP-based classification (i.e. dsmonAggGroup). Refer to Table 1 for a comparison of DSMON indexing structure with similar existing RMON features.

Table 1: DSMON Indexing Comparison

## dsmonMaxAggGroups OBJECT-TYPE

SYNTAX Integer32 (2..64)

MAX-ACCESS read-only

STATUS current

## DESCRIPTION

"The maximum number of counter aggregation groups that this agent can support. The agent will allow this number of distinct groups to be configured in the dsmonAggProfileTable, numbered from '0' to 'dsmonMaxAggGroups - 1', for each counter aggregation profile entry supported by the agent.

The agent MUST NOT lower this value during system operation, and SHOULD set this object to an appropriate value during system initialization."

```
::= { dsmonAggObjects 1 }
```

## dsmonAggControlLocked OBJECT-TYPE

SYNTAX TruthValue

MAX-ACCESS read-write

STATUS current

## DESCRIPTION

"Controls the setup of counter aggregation groups for this agent.

If this object contains the value 'true', then write access to the objects in the dsmonAggControlTable (except the dsmonAggControlOwner object), dsmonAggProfileTable, and dsmonAggGroupTable is not permitted, and data collection is possible. This object only controls write access to these MIB objects. The DSMON data collection control tables (e.g., dsmonHostCtlTable) can be configured at any time, regardless of the value of this object.

If this object contains the value 'false', write access to the objects in the dsmonAggControlTable, dsmonAggProfileTable, and dsmonAggGroupTable is permitted, and data collection is not possible. In addition, all objects in all DSMON data tables (e.g., dsmonStatsTable) shall be deleted.

An agent is not required to process SNMP Set Requests for this object in conjunction with other objects from this MIB. This is intended to simplify the processing of Set Requests for tables such as the dsmonAggProfileTable, by eliminating the possibility that a single Set PDU will contain multiple varbinds which are in conflict, such as a PDU which both modifies the dsmonAggProfileTable and locks the

dsmonAggProfileTable at the same time.

Note that the agent is not required to validate the entire counter aggregation configuration when an attempt is made to transition an instance of this object from 'true' to 'false'. That validation is done if and when a DSMON data collection is activated.

An agent is required to reactivate any suspended data collections when this object transitions to 'true'. Each active data control entry (e.g., dsmonStatsControlEntry), will be validated with respect to the new counter aggregation configuration. If the counter aggregation profile referenced in the data collection is valid, then that collection will be restarted. Otherwise, the RowStatus object (e.g., dsmonStatsControlStatus) will be set to 'notReady' for that collection control entry."

```
::= { dsmonAggObjects 2 }
```

dsmonAggControlChanges OBJECT-TYPE

SYNTAX Counter32

MAX-ACCESS read-only

STATUS current

DESCRIPTION

"This object counts the number of times the value of the dsmonAggControlLocked object has changed. A management station can use this object to detect if counters in the DSMON data tables (e.g., dsmonStatsEntry) have been deleted and recreated between polls.

This object shall be incremented by one each time the dsmonAggControlLocked object changes from 'false' to 'true', or from 'true' to 'false'."

```
::= { dsmonAggObjects 3 }
```

dsmonAggControlLastChangeTime OBJECT-TYPE

SYNTAX TimeStamp

MAX-ACCESS read-only

STATUS current

DESCRIPTION

"This object identifies the value of sysUpTime at the moment the dsmonAggControlLocked object was last modified. A management station can use this object to detect if counters in the DSMON data tables (e.g., dsmonStatsEntry) have been deleted and recreated between polls.

This object shall be updated with the current value of sysUpTime, if the dsmonAggControlLocked object changes from

'false' to 'true', or from 'true' to 'false'.

Upon system initialization, this object shall contain the value zero."

MAX-ACCESS not-accessible
```

```
STATUS current
```

```
DESCRIPTION
```

"This table provides an overall description and control point for all dsmonAggProfileEntries with the same dsmonAggControlIndex value.

A management application SHOULD create a counter aggregation profile by first creating and activating an entry in this table. This will cause the agent to create a set of 64 dsmonAggProfileEntries on behalf of this control entry. An application can then set the individual counter aggregation group assignments for each of the 64 DSCP values,

This table MUST NOT be modified if the dsmonAggControlLocked object is equal to 'true'.

Note that an agent MAY choose to limit the actual number of entries which may be created in this table, and (independently) the number of counter aggregation profiles which may be applied to a particular data source. In this case, the agent SHOULD return an error-status of 'resourceUnavailable(13)', as per section 4.2.5 of the 'Protocol Operations for SNMPv2' specification [RFC1905].

The agent SHOULD support non-volatile configuration of this table, and upon system initialization, the table SHOULD be initialized with the saved values. Otherwise, each potential counter aggregation group description string SHOULD contain the empty string."

```
STATUS      current
```

```
DESCRIPTION
```

"A list of information on Differentiated Services DSCP usage, containing packet and octet counters for each counter aggregation group configured for collection, and each protocol (as identified by the protocolDirLocalIndex for the protocol) identified in each monitored packet.

The dsmonPdistCtlIndex value in the index identifies the dsmonPdistCtlEntry on whose behalf this entry was created.

Note that only packets that contain a network protocol encapsulation which contains a DS field [RFC2474] will be counted in this table.

The dsmonAggGroupIndex value in the index is determined by examining the DSCP value in each monitored packet, and the dsmonAggProfileTable entry for that value.

The protocolDirLocalIndex in the index identifies the protocolDirEntry for the protocol encapsulation of each monitored packet. The agent will include only application layer protocols in the associated dsmonPdistStatsTable. Any 'terminal' protocol is considered to be an application protocol.

An example of the indexing of this entry is dsmonPdistStatsPkts.9.29943.0.42."

```

dsmonPdistTopNctlTimeRemaining OBJECT-TYPE

SYNTAX Integer32 (0..2147483647)

UNITS "seconds"

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"The number of seconds left in the report currently being collected. When this object is modified by the management station, a new collection is started, possibly aborting a currently running report. The new value is used as the requested duration of this report, and is immediately loaded into the associated dsmonPdistTopNctlDuration object.

When the report finishes, the probe will automatically start another collection with the same initial value of dsmonPdistTopNctlTimeRemaining. Thus the management station may simply read the resulting reports repeatedly, checking the startTime and duration each time to ensure that a report was not missed or that the report parameters were not changed.

While the value of this object is non-zero, it decrements by one per second until it reaches zero. At the time that this object decrements to zero, the report is made accessible in the dsmonPdistTopNTable, overwriting any report that may be there.

When this object is modified by the management station, any associated entries in the dsmonPdistTopNTable shall be deleted."

```

#### dsmonHostCtlDroppedFrames OBJECT-TYPE

SYNTAX Counter32

UNITS "frames"

MAX-ACCESS read-only

STATUS current

#### DESCRIPTION

"The total number of frames which were received by the probe and therefore not accounted for in the \*StatsDropEvents, but for which the probe chose not to count for the associated dsmonHost entries for whatever reason. Most often, this event occurs when the probe is out of some resources and decides to shed load from this collection.

This count does not include packets that were not counted because they had MAC-layer errors.

Note that if the dsmonHostTable is inactive because no appropriate protocols are enabled in the protocol directory, this value SHOULD be 0.

Note that, unlike the dropEvents counter, this number is the exact number of frames dropped."

```
::= { dsmonHostCtlEntry 7 }
```

#### dsmonHostCtlInserts OBJECT-TYPE

SYNTAX Counter32

UNITS "table entries"

MAX-ACCESS read-only

STATUS current

#### DESCRIPTION

"The number of times a dsmonHost entry has been inserted into the dsmonHost table. If an entry is inserted, then deleted, and then inserted, this counter will be incremented by 2.

To allow for efficient implementation strategies, agents MAY delay updating this object for short periods of time. For example, an implementation strategy may allow internal data structures to differ from those visible via SNMP for short periods of time. This counter may reflect the internal data structures for those short periods of time.

Note that the table size can be determined by subtracting dsmonHostCtlDeletes from dsmonHostCtlInserts."

```

## dsmonHostTable OBJECT-TYPE

SYNTAX SEQUENCE OF DsmonHostEntry

MAX-ACCESS not-accessible

STATUS current

## DESCRIPTION

"A collection of statistics for particular network protocols which contain a DS field, and that has been discovered on a particular dataSource.

The probe will add to this table all appropriate network protocols, for each network address seen as the source or destination address in all packets with no MAC errors, and will increment octet and packet counts in the table for all packets with no MAC errors.

If the dsmonAggControlLocked object is equal to 'false', then all entries in this table will be deleted, and the agent will not process packets on behalf of any dsmonHostCtlEntry."

```
::= { dsmonHostObjects 2 }
```

## dsmonHostEntry OBJECT-TYPE

SYNTAX DsmonHostEntry

MAX-ACCESS not-accessible

STATUS current

## DESCRIPTION

"A list of information on Differentiated Services DSCP usage, containing packet and octet counters for each counter aggregation group index configured for collection per host address, as identified in the dsmonAggProfileTable.

The dsmonHostCtlIndex value in the index identifies the dsmonHostCtlEntry on whose behalf this entry was created.

The protocolDirLocalIndex value in the index identifies the specific network layer protocol encapsulation associated with each entry, and the network protocol type of the dsmonHostAddress object. It MUST identify a protocolDirEntry which contains a DS field (e.g., IPv4 or IPv6). Note that if a protocol encapsulation with multiple network layers is specified, then associated entries in this table refer to the innermost network protocol layer host address.

The dsmonAggGroupIndex value in the index is determined by examining the DSCP value in each monitored packet, and the dsmonAggProfileTable entry configured for that value.

An example of the indexing of this entry is  
dsmonHostOutPkts.1.27273.3.200.4.171.69.120.0"

```
INDEX { dsmonHostCtlIndex,

        dsmonHostTopNTotalHCPkts(11),
        dsmonHostTopNTotalHCOctets(12)
    }
MAX-ACCESS read-create
STATUS current
DESCRIPTION
    "The variable(s) for each dsmonHost that the
    dsmonHostTopNRate and dsmonHostTopNHCRate variables are
    based upon. Each dsmonHostTopN report generated on behalf
    of this control entry will be ranked in descending order,
    based on the associated dsmonHostTable counter(s),
    identified by this object.
```

The following table identifies the dsmonHostTable counters associated with each enumeration:

Enumeration	RateBase MIB Objects
-----	-----
dsmonHostTopNInPkts	dsmonHostInPkts
dsmonHostTopNInOctets	dsmonHostInOctets
dsmonHostTopNOutPkts	dsmonHostOutPkts
dsmonHostTopNOutOctets	dsmonHostOutOctets
dsmonHostTopNTotalPkts	dsmonHostInPkts + dsmonHostOutPkts
dsmonHostTopNTotalOctets	dsmonHostInOctets + dsmonHostOutOctets
dsmonHostTopNInHCPkts	dsmonHostInHCPkts
dsmonHostTopNInHCOctets	dsmonHostInHCOctets
dsmonHostTopNOutHCPkts	dsmonHostOutHCPkts
dsmonHostTopNOutHCOctets	dsmonHostOutHCPkts
dsmonHostTopNTotalHCPkts	dsmonHostInHCPkts + dsmonHostOutHCPkts
dsmonHostTopNTotalHCOctets	dsmonHostInHCOctets + dsmonHostOutHCOctets

The following enumerations are only available if the agent supports High Capacity monitoring:

```

dsmonHostTopNInHCPkts
dsmonHostTopNInHCOctets
```

```

dsmonHostTopNOutHCPkts
dsmonHostTopNOutHCOctets
dsmonHostTopNTotalHCPkts
dsmonHostTopNTotalHCOctets

```

It is an implementation-specific matter whether an agent can detect an overflow condition resulting from the addition of two counter delta values for the following enumerations:

```

dsmonHostTopNTotalPkts
dsmonHostTopNTotalOctets
dsmonHostTopNTotalHCPkts
dsmonHostTopNTotalHCOctets

```

In the event such an overflow condition can be detected by the agent, the associated dsmonHostTopNRate, dsmonHostTopNRateOvfl, and/or dsmonHostTopNHCRate objects should be set to their maximum value.

```

This object MUST NOT be modified if the associated
dsmonHostTopNctlStatus object is equal to active(1)."
 ::= { dsmonHostTopNctlEntry 3 }

```

dsmonHostTopNctlTimeRemaining OBJECT-TYPE

SYNTAX Integer32 (0..2147483647)

UNITS "seconds"

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"The number of seconds left in the report currently being collected. When this object is modified by the management station, a new collection is started, possibly aborting a currently running report. The new value is used as the requested duration of this report, and is immediately loaded into the associated dsmonHostTopNctlDuration object.

When the report finishes, the probe will automatically start another collection with the same initial value of dsmonHostTopNctlTimeRemaining. Thus the management station may simply read the resulting reports repeatedly, checking the startTime and duration each time to ensure that a report was not missed or that the report parameters were not changed.

While the value of this object is non-zero, it decrements by one per second until it reaches zero. At the time that this object decrements to zero, the report is made accessible in the dsmonHostTopNTable, overwriting any report that may be

there.

When this object is modified by the management station, any associated entries in the dsmonHostTopNTable shall be deleted."

```

## dsmonMatrixCtlMaxDesiredEntries OBJECT-TYPE

SYNTAX Integer32 (-1 | 1..2147483647)

UNITS "table entries"

MAX-ACCESS read-create

STATUS current

## DESCRIPTION

"The maximum number of entries that are desired in the dsmonMatrix tables on behalf of this control entry. The probe will not create more than this number of associated entries in these tables, but may choose to create fewer entries in this table for any reason including the lack of resources.

If this value is set to -1, the probe may create any number of entries in this table.

This object MUST NOT be modified if the associated dsmonMatrixCtlStatus object is equal to active(1)."

```
::= { dsmonMatrixCtlEntry 4 }
```

## dsmonMatrixCtlDroppedFrames OBJECT-TYPE

SYNTAX Counter32

UNITS "frames"

MAX-ACCESS read-only

STATUS current

## DESCRIPTION

"The total number of frames which were received by the probe and therefore not accounted for in the \*StatsDropEvents, but for which the probe chose not to count for the associated dsmonMatrixSD and dsmonMatrixDS entries for whatever reason. Most often, this event occurs when the probe is out of some resources and decides to shed load from this collection.

This count does not include packets that were not counted because they had MAC-layer errors.

Note that if the dsmonMatrix tables are inactive because no appropriate protocols are enabled in the protocol directory, this value SHOULD be 0.

Note that, unlike the dropEvents counter, this number is the exact number of frames dropped."

```
::= { dsmonMatrixCtlEntry 5 }
```

## dsmonMatrixCtlInserts OBJECT-TYPE

SYNTAX Counter32

UNITS "table entries"

MAX-ACCESS read-only

STATUS current

DESCRIPTION

"The number of times a dsmonMatrix entry has been inserted into the dsmonMatrix tables. If an entry is inserted, then deleted, and then inserted, this counter will be incremented by 2. The addition of a conversation into both the dsmonMatrixSDTable and dsmonMatrixDSTable shall be counted as two insertions (even though every addition into one table must be accompanied by an insertion into the other).

To allow for efficient implementation strategies, agents may delay updating this object for short periods of time. For example, an implementation strategy may allow internal data structures to differ from those visible via SNMP for short periods of time. This counter may reflect the internal data structures for those short periods of time. Note that the sum of the dsmonMatrixSDTable and dsmonMatrixDSTable sizes can be determined by subtracting dsmonMatrixCtlDeletes from dsmonMatrixCtlInserts."

## dsmonMatrixTopNctlTable OBJECT-TYPE

SYNTAX SEQUENCE OF DsmonMatrixTopNctlEntry

MAX-ACCESS not-accessible

STATUS current

## DESCRIPTION

"A set of parameters that control the creation of a report of the top N dsmonMatrix entries according to a selected metric.

Note that an agent MAY choose to limit the actual number of entries which may be created in this table. In this case, the agent SHOULD return an error-status of 'resourceUnavailable(13)', as per section 4.2.5 of the 'Protocol Operations for SNMPv2' specification [RFC1905]."

```
::= { dsmonMatrixObjects 4 }
```

## dsmonMatrixTopNctlEntry OBJECT-TYPE

SYNTAX DsmonMatrixTopNctlEntry

MAX-ACCESS not-accessible

STATUS current

## DESCRIPTION

"A conceptual row in the dsmonMatrixTopNctlTable.

Entries are created and deleted from this table by management action only, using the dsmonMatrixTopNctlStatus RowStatus object.

The agent SHOULD support non-volatile configuration of this table, and upon system initialization, the table SHOULD be initialized with the saved values.

Activation of a control row in this table will cause an associated dsmonMatrixTopNTable to be created and maintained by the agent."

```
INDEX { dsmonMatrixTopNctlIndex }
```

```
::= { dsmonMatrixTopNctlTable 1 }
```

## DsmonMatrixTopNctlEntry ::= SEQUENCE {

dsmonMatrixTopNctlIndex Integer32,

STATUS current

DESCRIPTION

"An index that uniquely identifies an entry in the dsmonMatrixTopNctlTable. Each such entry defines one Top N report prepared for one RMON dataSource."

::= { dsmonMatrixTopNctlEntry 1 }

dsmonMatrixTopNctlMatrixIndex OBJECT-TYPE

SYNTAX Integer32 (1..65535)

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"The dsmonMatrixSDTable for which a top N report will be prepared on behalf of this entry. The dsmonMatrixSDTable is identified by the same value of the dsmonMatrixCtlIndex object.

This object MUST NOT be modified if the associated dsmonMatrixTopNctlStatus object is equal to active(1)."

::= { dsmonMatrixTopNctlEntry 2 }

dsmonMatrixTopNctlRateBase OBJECT-TYPE

SYNTAX INTEGER {  
     dsmonMatrixTopNPkts(1),  
     dsmonMatrixTopNOctets(2),  
     dsmonMatrixTopNHCPkts(3),  
     dsmonMatrixTopNHCOctets(4)  
 }

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"The variable for each dsmonMatrixSD entry that the dsmonMatrixTopNRate and dsmonMatrixTopNHCRate variables are based upon. Each dsmonMatrixTopN report generated on behalf of this control entry will be ranked in descending order, based on the associated dsmonMatrixSDTable counter, identified by this object.

The following table identifies the dsmonMatrixSDTable counters associated with each enumeration:

Enumeration	RateBase MIB Objects
-------------	----------------------

```

-----
dsmonMatrixTopNPkts          dsmonMatrixSDPkts
dsmonMatrixTopNOctets       dsmonMatrixSDOctets
dsmonMatrixTopNHCPkts       dsmonMatrixSDHCPkts
dsmonMatrixTopNHCOctets     dsmonMatrixSDHCOctets

```

The following enumerations are only available if the agent supports High Capacity monitoring:

```

dsmonMatrixTopNHCPkts
dsmonMatrixTopNHCOctets

```

This object MUST NOT be modified if the associated dsmonMatrixTopNctlStatus object is equal to active(1)."

```
 ::= { dsmonMatrixTopNctlEntry 3 }
```

dsmonMatrixTopNctlTimeRemaining OBJECT-TYPE

SYNTAX Integer32 (0..2147483647)

UNITS "seconds"

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"The number of seconds left in the report currently being collected. When this object is modified by the management station, a new collection is started, possibly aborting a currently running report. The new value is used as the requested duration of this report, and is immediately loaded into the associated dsmonMatrixTopNctlDuration object.

When the report finishes, the probe will automatically start another collection with the same initial value of dsmonMatrixTopNctlTimeRemaining. Thus the management station may simply read the resulting reports repeatedly, checking the startTime and duration each time to ensure that a report was not missed or that the report parameters were not changed.

While the value of this object is non-zero, it decrements by one per second until it reaches zero. At the time that this object decrements to zero, the report is made accessible in the dsmonMatrixTopNTable, overwriting any report that may be there.

When this object is modified by the management station, any associated entries in the dsmonMatrixTopNTable shall be deleted."

```
DEFVAL { 1800 }
```

```
 ::= { dsmonMatrixTopNctlEntry 4 }
```

## dsmonMatrixTopNctlGeneratedRpts OBJECT-TYPE

## 5. Counter Aggregation Configuration Usage Examples

This section contains an example of the steps that may be followed by a management station to configure the objects in the dsmonCounterAggControlGroup.

A note about these examples:

- they do not define a standard
- an agent is not obligated to support them
- a management application is not constrained by them
- the SET(object = value [, ...]) notation is only conceptual, and is not meant to represent an actual SNMP Set PDU.

### 5.1. Step 1: Unlock the Counter Aggregation Configuration

Before any write operations to the tabular objects in this group can be made, the counter aggregation configuration must be unlocked by setting the `dsmonAggControlLocked` scalar to false:

```
SET(dsmonAggControlLocked.0 = false(2));
```

### 5.2. Step 2: Check the Maximum number of Counter Aggregation Groups

Make sure the desired counter aggregation groups have a chance of being configured on the agent.

```
maxGroups = GET(dsmonAggMaxAggGroups.0);
```

For this example, `maxGroups` is greater or equal to 64.

### 5.3. Step 3: Check if the counter aggregation profiles already exist

Make sure the desired counter aggregation profiles have not already been configured, or perhaps recreated after an agent restart. The following example is oversimplified, in that the entire counter aggregation configuration should actually be verified.

```
profile1Descr = GET(dsmonAggControlDescr.1);  
profile1Owner = GET(dsmonAggControlOwner.1);  
profile1Status = GET(dsmonAggControlStatus.1);
```

For this example, none of the counter aggregation profiles already exist.

### 5.4. Step 4: Create the Counter Aggregation Control Entries

The management station should create one entry in the `dsmonAggControlTable` for each counter aggregation profile to be configured on the agent.

Steps 4, 5, and 6 are repeated for each counter aggregation profile to be configured on the agent. There are 3 example counter aggregation profiles shown in each of these steps.

Example 1: Each DSCP in its own counter aggregation group.

```
SET(dsmonAggControlStatus.1 = createAndGo(4),  
    dsmonAggControlOwner.1 = "Example App 1",  
    dsmonAggControlDescr.1 = "1 DSCP Per Group");
```

Example 2: a collection of DIFFSERV PHBs.

```
SET(dsmonAggControlStatus.2 = createAndGo(4),
    dsmonAggControlOwner.2 = "Example App 2",
    dsmonAggControlDescr.2 = "June 2000 DIFFSERV PHBs");
```

Example 3: an aggregated collection of DIFFSERV PHBs.

```
SET(dsmonAggControlStatus.3 = createAndGo(4),
    dsmonAggControlOwner.3 = "Example App 3",
    dsmonAggControlDescr.3 = "Limited June 2000 PHBs");
```

#### 5.5. Step 5: Create the Counter Aggregation Group Descriptions

Example 1: Each DSCP in its own counter aggregation group. One group is created for each codepoint, for a total of 64 rows.

```
SET(dsmonAggGroupStatus.1.0 = createAndGo(4),
    dsmonAggGroupDescr.1.0 = "DSCP 0");
SET(dsmonAggGroupStatus.1.1 = createAndGo(4),
    dsmonAggGroupDescr.1.1 = "DSCP 1");
SET(dsmonAggGroupStatus.1.2 = createAndGo(4),
    dsmonAggGroupDescr.1.2 = "DSCP 2");
SET(dsmonAggGroupStatus.1.3 = createAndGo(4),
    dsmonAggGroupDescr.1.3 = "DSCP 3");

...

SET(dsmonAggGroupStatus.1.63 = createAndGo(4),
    dsmonAggGroupDescr.1.63 = "DSCP 63");
```

Example 2: a collection of current DIFFSERV PHBs. One group is created for each PHB to be monitored.

```
SET(dsmonAggGroupStatus.2.0 = createAndGo(4),
    dsmonAggGroupDescr.2.0 = "CS0");
SET(dsmonAggGroupStatus.2.1 = createAndGo(4),
    dsmonAggGroupDescr.2.1 = "CS1");
SET(dsmonAggGroupStatus.2.2 = createAndGo(4),
    dsmonAggGroupDescr.2.2 = "CS2");
SET(dsmonAggGroupStatus.2.3 = createAndGo(4),
    dsmonAggGroupDescr.2.3 = "CS3");
SET(dsmonAggGroupStatus.2.4 = createAndGo(4),
    dsmonAggGroupDescr.2.4 = "CS4");
SET(dsmonAggGroupStatus.2.5 = createAndGo(4),
    dsmonAggGroupDescr.2.5 = "CS5");
SET(dsmonAggGroupStatus.2.6 = createAndGo(4),
    dsmonAggGroupDescr.2.6 = "CS6");
SET(dsmonAggGroupStatus.2.7 = createAndGo(4),
    dsmonAggGroupDescr.2.7 = "CS7");
SET(dsmonAggGroupStatus.2.8 = createAndGo(4),
    dsmonAggGroupDescr.2.8 = "EF");
SET(dsmonAggGroupStatus.2.9 = createAndGo(4),
    dsmonAggGroupDescr.2.9 = "AF11");
SET(dsmonAggGroupStatus.2.10 = createAndGo(4),
    dsmonAggGroupDescr.2.10 = "AF12");
SET(dsmonAggGroupStatus.2.11 = createAndGo(4),
    dsmonAggGroupDescr.2.11 = "AF13");
SET(dsmonAggGroupStatus.2.12 = createAndGo(4),
    dsmonAggGroupDescr.2.12 = "AF21");
SET(dsmonAggGroupStatus.2.13 = createAndGo(4),
    dsmonAggGroupDescr.2.13 = "AF22");
SET(dsmonAggGroupStatus.2.14 = createAndGo(4),
    dsmonAggGroupDescr.2.14 = "AF23");
SET(dsmonAggGroupStatus.2.15 = createAndGo(4),
    dsmonAggGroupDescr.2.15 = "AF31");
SET(dsmonAggGroupStatus.2.16 = createAndGo(4),
    dsmonAggGroupDescr.2.16 = "AF32");
SET(dsmonAggGroupStatus.2.17 = createAndGo(4),
    dsmonAggGroupDescr.2.17 = "AF33");
SET(dsmonAggGroupStatus.2.18 = createAndGo(4),
    dsmonAggGroupDescr.2.18 = "AF41");
SET(dsmonAggGroupStatus.2.19 = createAndGo(4),
    dsmonAggGroupDescr.2.19 = "AF42");
SET(dsmonAggGroupStatus.2.20 = createAndGo(4),
    dsmonAggGroupDescr.2.20 = "AF43");
SET(dsmonAggGroupStatus.2.21 = createAndGo(4),
    dsmonAggGroupDescr.2.21 = "Nonzero Default");
```

Example 3: an aggregated representation of current DIFFSERV PHBs. One group is created for each counter aggregation to be monitored (8 rows in this example).

```
SET(dsmonAggGroupStatus.3.0 = createAndGo(4),
    dsmonAggGroupDescr.3.0 = "Zero CS");
SET(dsmonAggGroupStatus.3.1 = createAndGo(4),
    dsmonAggGroupDescr.3.1 = "Nonzero CS");
SET(dsmonAggGroupStatus.3.2 = createAndGo(4),
    dsmonAggGroupDescr.3.2 = "EF");
SET(dsmonAggGroupStatus.3.3 = createAndGo(4),
    dsmonAggGroupDescr.3.3 = "AF1");
SET(dsmonAggGroupStatus.3.4 = createAndGo(4),
    dsmonAggGroupDescr.3.4 = "AF2");
SET(dsmonAggGroupStatus.3.5 = createAndGo(4),
    dsmonAggGroupDescr.3.5 = "AF3");
SET(dsmonAggGroupStatus.3.6 = createAndGo(4),
    dsmonAggGroupDescr.3.6 = "AF4");
SET(dsmonAggGroupStatus.3.7 = createAndGo(4),
    dsmonAggGroupDescr.3.7 = "Nonzero Default");
```

#### 5.6. Step 6: Create the Counter Aggregation Profile Mappings

After the dsmonAggControlEntries are activated, the associated read-write dsmonAggProfileEntries will be created. The management station must create 64 entries in the dsmonAggProfileTable for each counter aggregation profile configured in the dsmonAggControlTable.

Example 1: Each DSCP in its own counter aggregation group

```
SET(dsmonAggGroupIndex.1.0 = 0,
    dsmonAggGroupIndex.1.1 = 1,
    dsmonAggGroupIndex.1.2 = 2,
    dsmonAggGroupIndex.1.3 = 3,
    ...
    dsmonAggGroupIndex.1.63 = 63);
```

Example 2: a collection of current DIFFSERV PHBs.

```
SET(dsmonAggGroupIndex.2.0 = 0,           -- CS0
    dsmonAggGroupIndex.2.1 = 21,         -- Nonzero Default
    dsmonAggGroupIndex.2.2 = 21,
    dsmonAggGroupIndex.2.3 = 21,
    dsmonAggGroupIndex.2.4 = 21,
    dsmonAggGroupIndex.2.5 = 21,
    dsmonAggGroupIndex.2.6 = 21,
    dsmonAggGroupIndex.2.7 = 21,
    dsmonAggGroupIndex.2.8 = 1,         -- CS1
```

```
dsmonAggGroupIndex.2.9 = 21,
dsmonAggGroupIndex.2.10 = 9,           -- AF11
dsmonAggGroupIndex.2.11 = 21,
dsmonAggGroupIndex.2.12 = 10,        -- AF12
dsmonAggGroupIndex.2.13 = 21,
dsmonAggGroupIndex.2.14 = 11,        -- AF13
dsmonAggGroupIndex.2.15 = 21,
dsmonAggGroupIndex.2.16 = 2,         -- CS2
dsmonAggGroupIndex.2.17 = 21,
dsmonAggGroupIndex.2.18 = 12,        -- AF21
dsmonAggGroupIndex.2.19 = 21,
dsmonAggGroupIndex.2.20 = 13,        -- AF22
dsmonAggGroupIndex.2.21 = 21,
dsmonAggGroupIndex.2.22 = 14,        -- AF23
dsmonAggGroupIndex.2.23 = 21,
dsmonAggGroupIndex.2.24 = 3,         -- CS3
dsmonAggGroupIndex.2.25 = 21,
dsmonAggGroupIndex.2.26 = 15,        -- AF31
dsmonAggGroupIndex.2.27 = 21,
dsmonAggGroupIndex.2.28 = 16,        -- AF32
dsmonAggGroupIndex.2.29 = 8,         -- EF
dsmonAggGroupIndex.2.30 = 17,        -- AF33
dsmonAggGroupIndex.2.31 = 21,
dsmonAggGroupIndex.2.32 = 4,         -- CS4

dsmonAggGroupIndex.3.61 = 7,  
dsmonAggGroupIndex.3.62 = 7,  
dsmonAggGroupIndex.3.63 = 7);
```

#### 5.7. Step 7: Lock the Counter Aggregation Configuration

Before any existing collections can be activated by the agent, the counter aggregation configuration must be locked, by setting the `dsmonAggControlLocked` scalar to 'true'.

```
SET(dsmonAggControlLocked.0 = true(1));
```

#### 6. Intellectual Property

The IETF takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on the IETF's procedures with respect to rights in standards-track and standards-related documentation can be found in BCP 11, RFC 2028. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of

such proprietary rights by implementors or users of this specification can be obtained from the IETF Secretariat.

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to practice this standard. Please address the information to the IETF Executive Director.

## 7. Acknowledgements

This memo is a product of the RMONMIB WG. It is based on an Internet Draft that was produced with a great deal of assistance from Keith McCloghrie and Bijendra Jain.

## 9. Security Considerations

In order to implement this MIB, a probe must capture all packets on the locally-attached network, including packets between third parties. These packets are analyzed to collect network addresses, protocol usage information, and conversation statistics. Data of this nature may be considered sensitive in some environments. In such environments the administrator may wish to restrict SNMP access to the probe.

There are a number of management objects defined in this MIB that have a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations.

SNMPv1 by itself is not a secure environment. Even if the network itself is secure (for example by using IPSec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB.

It is recommended that the implementors consider the security features as provided by the SNMPv3 framework. Specifically, the use of the User-based Security Model RFC 2574 [RFC2574] and the View-based Access Control Model RFC 2575 [RFC2575] is recommended.

It is then a customer/user responsibility to ensure that the SNMP entity giving access to an instance of this MIB, is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.
