Abstract

   This memo defines a portion of the Management Information Base (MIB)
   for use with network management protocols in the Internet community.
   In particular, it describes a set of managed objects that are used to
   schedule management operations periodically or at specified dates and
   times.

   This document obsoletes RFC 2591.

Table of Contents

1. Introduction

   This memo defines a portion of the Management Information Base (MIB)
   for use with network management protocols in the Internet community.
   In particular, it describes a set of managed objects that are used to
   schedule management operations periodically or at specified dates and
   times.

   The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
   "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this
   document are to be interpreted as described in RFC 2119 [RFC2119].

2. The SNMP Management Framework

   The SNMP Management Framework presently consists of five major
   components:

   o An overall architecture, described in RFC 2571 [RFC2571].

   o Mechanisms for describing and naming objects and events for the
      purpose of management. The first version of this Structure of
      Management Information (SMI) is called SMIv1 and described in STD
      16, RFC 1155 [RFC1155], STD 16, RFC 1212 [RFC1212] and RFC 1215
      [RFC1215]. The second version, called SMIv2, is described in STD
      58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC
      2580 [RFC2580].

   o Message protocols for transferring management information. The
      first version of the SNMP message protocol is called SNMPv1 and
      described in STD 15, RFC 1157 [RFC1157]. A second version of the
      SNMP message protocol, which is not an Internet standards track
      protocol, is called SNMPv2c and described in RFC 1901 [RFC1901]
      and RFC 1906 [RFC1906]. The third version of the message protocol
      is called SNMPv3 and described in RFC 1906 [RFC1906], RFC 2572
      [RFC2572] and RFC 2574 [RFC2574].

   o Protocol operations for accessing management information. The
      first set of protocol operations and associated PDU formats is
      described in STD 15, RFC 1157 [RFC1157]. A second set of protocol
      operations and associated PDU formats is described in RFC 1905
      [RFC1905].

   o A set of fundamental applications described in RFC 2573 [RFC2573]
      and the view-based access control mechanism described in RFC 2575
      [RFC2575].

   A more detailed introduction to the current SNMP Management Framework
   can be found in RFC 2570 [RFC2570].

   Managed objects are accessed via a virtual information store, termed
   the Management Information Base or MIB. Objects in the MIB are
   defined using the mechanisms defined in the SMI.

   This memo specifies a MIB module that is compliant to the SMIv2. A
   MIB conforming to the SMIv1 can be produced through the appropriate
   translations. The resulting translated MIB must be semantically
   equivalent, except where objects or events are omitted because no
   translation is possible (use of Counter64). Some machine readable
   information in SMIv2 will be converted into textual descriptions in
   SMIv1 during the translation process. However, this loss of machine
   readable information is not considered to change the semantics of the
   MIB.

3. Overview

   The MIB defined in this memo provides the scheduling of actions
   periodically or at specified dates and times. The actions can be
   used to realize on-duty / off-duty schedules or to trigger management
   functions in a distributed management application.

   Schedules can be enabled or disabled by modifying a control object.
   This allows for pre-configured schedules which are activated or
   deactivated by some other management functions.

   The term 'scheduler' is used throughout this memo to refer to the
   entity which implements the scheduling MIB and which invokes the
   actions at the specified points in time.

3.1. Periodic Schedules

   Periodic schedules are based on fixed time periods between the
   initiation of scheduled actions. Periodic schedules are defined by
   specifying the number of seconds between two initiations. The time
   needed to complete the action is usually not known by the scheduler
   and does therefore not influence the next scheduling point.

   Implementations must guarantee that action invocations will not occur
   before their next scheduled time. However, implementations may be
   forced to delay invocations in the face of local constraints (e.g., a
   heavy load on higher-priority tasks). An accumulation of such delays
   would result in a drift of the scheduling interval with respect to
   time, and should be avoided.

   Scheduled actions collecting statistical data should retrieve time
   stamps from the data source and not rely on the accuracy of the
   periodic scheduler in order to obtain accurate statistics.

3.2. Calendar Schedules

   Calendar schedules trigger scheduled actions at specified days of the
   week and days of the month. Calendar schedules are therefore aware
   of the notion of months, days, weekdays, hours and minutes.

   It is possible to specify multiple values for each calendar item.
   This provides a mechanism for defining complex schedules. For
   example, a schedule could be defined which triggers an action every
   15 minutes on a given weekday.

   Months, days and weekdays are specified using the objects schedMonth,
   schedDay and schedWeekDay of type BITS. Setting multiple bits to one
   in these objects causes an OR operation. For example, setting the
   bits monday(1) and friday(5) in schedWeekDay restricts the schedule
   to Mondays and Fridays.

   The bit fields for schedMonth, schedDay and schedWeekDay are combined
   using an AND operation. For example, setting the bits june(5) and
   july(6) in schedMonth and combining it with the bits monday(1) and
   friday(5) set in schedWeekDay will result in a schedule which is
   restricted to every Monday and Friday in the months June and July.
   Wildcarding of calendar items is achieved by setting all bits to one.

   It is possible to define calendar schedules that will never trigger
   an action. For example, one can define a calendar schedule which
   should trigger an action on February 31st. Schedules like this will
   simply be ignored by the scheduler.

Finally, calendar schedules are always expressed in local time. A
scalar, schedLocalTime, is provided so that a manager can retrieve
the notion of local time and the offset to GMT time.

3.3. One-shot Schedules

One-shot Schedules are similar to calendar schedules. The difference
between a calendar schedule and a one-shot schedule is that a one-
shot schedule will automatically disable itself once an action has
been invoked.

3.4. Time Transitions

A time transition occurs when the Schedule MIB's notion of time (as
reported by schedLocalTime) is changed so that time continuity is
lost. Time transitions may be caused by daylight savings times or
administrative changes of the system's notion of time.

There are two possible situations when a time transition occurs.

First, time may be set backwards, in which case particular times will
appear to occur twice. These are called 'ambiguous times'. Second,
time may be set forwards, in which case particular times will not
occur. These are called 'nonexistent times'.

When an action is configured in the Schedule MIB to occur at an
ambiguous time, the action will be invoked at all occurrences of the
ambiguous time. For example, if an action is scheduled to occur at
2:10 am, and a time transition occurs at 3:00 am which sets the clock
back to 2:00 am, the action will be invoked twice.

When an action is configured in the Schedule MIB to occur at a
nonexistent time, the action will not be invoked at all. For
example, if an action is scheduled to occur at 2:10 am, and a time
transition occurs at 2:00 am which sets the clock to 3:00 am, the
action will not be invoked.

3.5. Actions

Scheduled actions are modeled by SNMP set operations on local MIB
variables. Scheduled actions described in this MIB are further
restricted to objects of type INTEGER. This restriction does not
limit the usefulness of the MIB. Simple schedules such as on-duty /
off-duty schedules for resources that have a status MIB object (e.g.
ifAdminStatus) are possible.

More complex actions can be realized by triggering a management
script which is responsible for performing complex state transitions.
A management script can also be used to perform SNMP set operations
on remote SNMP engines.

        DESCRIPTION
            "The locally-unique, administratively assigned name for this
             scheduling entry.  This object allows a schedOwner to have
             multiple entries in the schedTable."
        ::= { schedEntry 2 }

    schedDescr OBJECT-TYPE
        SYNTAX        SnmpAdminString
        MAX-ACCESS    read-create
        STATUS        current
        DESCRIPTION
            "The human readable description of the purpose of this
             scheduling entry."
        DEFVAL        { "" }
        ::= { schedEntry 3 }

    schedInterval OBJECT-TYPE
        SYNTAX        Unsigned32
        UNITS         "seconds"
        MAX-ACCESS    read-create
        STATUS        current
        DESCRIPTION
            "The number of seconds between two action invocations of
             a periodic scheduler.  Implementations must guarantee
             that action invocations will not occur before at least
             schedInterval seconds have passed.

             The scheduler must ignore all periodic schedules that
             have a schedInterval value of 0.  A periodic schedule
             with a scheduling interval of 0 seconds will therefore
             never invoke an action.

             Implementations may be forced to delay invocations in the
             face of local constraints.  A scheduled management function
             should therefore not rely on the accuracy provided by the
             scheduler implementation.

             Note that implementations which maintain a list of pending
             activations must re-calculate them when this object is
             changed."

                        r11(41), r12(42), r13(43), r14(44), r15(45),
                        r16(46), r17(47), r18(48), r19(49), r20(50),
                        r21(51), r22(52), r23(53), r24(54), r25(55),
                        r26(56), r27(57), r28(58), r29(59), r30(60),
                        r31(61)
                      }
        MAX-ACCESS read-create
        STATUS   current
        DESCRIPTION
            "The set of days in a month on which a scheduled action
             should take place. There are two sets of bits one can
             use to define the day within a month:

             Enumerations starting with the letter 'd' indicate a
             day in a month relative to the first day of a month.
             The first day of the month can therefore be specified
             by setting the bit d1(0) and d31(30) means the last
             day of a month with 31 days.

             Enumerations starting with the letter 'r' indicate a
             day in a month in reverse order, relative to the last
             day of a month. The last day in the month can therefore
             be specified by setting the bit r1(31) and r31(61) means
             the first day of a month with 31 days.

             Setting multiple bits will include several days in the set
             of possible days for this schedule. Setting all bits will
             cause the scheduler to ignore the day within a month.

```
        Setting all bits starting with the letter 'd' or the
        letter 'r' will also cause the scheduler to ignore the
        day within a month.

        Note that implementations which maintain a list of pending
        activations must re-calculate them when this object is
        changed."

        STATUS   current
        DESCRIPTION
            "The value which is written to the MIB object pointed to by
             schedVariable when the scheduler invokes an action. The
             implementation shall enforce the use of access control
             rules when performing the set operation on schedVariable.
             This is accomplished by calling the isAccessAllowed abstract
             service interface as defined in RFC 2571.

             Note that an implementation may choose to issue an SNMP Set
             message to the SNMP engine and leave the access control
             decision to the normal message processing procedure."
        DEFVAL   { 0 }
        ::= { schedEntry 12 }

    schedType OBJECT-TYPE

```
     SYNTAX       INTEGER {
                     periodic(1),
                     calendar(2),
                     oneshot(3)
                 }
     MAX-ACCESS   read-create
     STATUS       current
     DESCRIPTION
         "The type of this schedule.  The value periodic(1) indicates
          that this entry specifies a periodic schedule.  A periodic
          schedule is defined by the value of schedInterval.  The
          values of schedWeekDay, schedMonth, schedDay, schedHour
          and schedMinute are ignored.

          The value calendar(2) indicates that this entry describes a
          calendar schedule.  A calendar schedule is defined by the
          values of schedWeekDay, schedMonth, schedDay, schedHour and
          schedMinute.  The value of schedInterval is ignored.  A
          calendar schedule will trigger on all local times that
          satisfy the bits set in schedWeekDay, schedMonth, schedDay,
          schedHour and schedMinute.

          The value oneshot(3) indicates that this entry describes a
          one-shot schedule.  A one-shot schedule is similar to a
          calendar schedule with the additional feature that it
          disables itself by changing in the 'finished'
          schedOperStatus once the schedule triggers an action.

          Note that implementations which maintain a list of pending
          activations must re-calculate them when this object is
          changed."

5. Usage Examples

   This section presents some examples how the scheduling MIB can be
   used to schedule scripts with the Script MIB [RFC3165] or to realize
   on-duty/off-duty schedules by modifying status objects of other MIB
   modules.

5.1. Starting a script to ping devices every 20 minutes

   It is assumed that the schedule entry is owned by schedOwner = "joe"
   and its name is schedName = "ping". The instance identifier for the
   scheduling entry is therefore 3.106.111.101.4.112.105.110.103.

   It is further assumed that the smLaunchTable entry is owned by
   smLaunchOwner = "joe" and its name is smLaunchName = "ping-devs".
   The complete object identifier for the smLaunchStart object is
   therefore
   smLaunchStart.3.106.111.101.9.112.105.110.103.45.100.101.118.115.
   The script lives in the context identified by the string "engine1".

The configuration of the scheduler entry which launches the script
every 20 minutes would look as follows:

```
schedInterval.3.106.111.101.4.112.105.110.103 = 1200

schedValue.3.106.111.101.4.112.105.110.103 = 0
schedContextName.3.106.111.101.4.112.105.110.103 = "engine1"
schedVariable.3.106.111.101.4.112.105.110.103 =
   smLaunchStart.3.106.111.101.9.112.105.110.103.45.100.101.118.115

schedType.3.106.111.101.4.112.105.110.103 = periodic(1)
schedAdminStatus.3.106.111.101.4.112.105.110.103 = enabled(1)
schedStorageType.3.106.111.101.4.112.105.110.103 = nonVolatile(3)
schedRowStatus.3.106.111.101.4.112.105.110.103 = active(1)
```

All the remaining columns in the schedTable represent status
information and are not shown here.

5.2. Starting a script at the next Friday the 13th

It is assumed that the schedule entry is owned by schedOwner = "joe"
and its name is schedName = "13th". The instance identifier for the
scheduling entry is therefore 3.106.111.101.4.49.51.116.104.

It is further assumed that the smLaunchTable entry is owned by
smLaunchOwner = "joe" and its name is smLaunchName = "ghost". The
complete object identifier for the smLaunchStart object is therefore
smLaunchStart.3.106.111.101.5.103.104.111.115.116. The script lives
in the context identified by the string "engine1".

The configuration of the scheduler entry which launches the script on
the next Friday 13th at midnight would look as follows:

```
schedWeekDay.3.106.111.101.4.49.51.116.104 = { friday }
schedMonth.3.106.111.101.4.49.51.116.104 = {
        january, february, march, april, may, june,
        july, august, september, october, november, december
}
schedDay.3.106.111.101.4.49.51.116.104 = { d13 }
schedHour.3.106.111.101.4.49.51.116.104 = { h0 }
schedMinute.3.106.111.101.4.49.51.116.104 = { m0 }

schedValue.3.106.111.101.4.49.51.116.104 = 0
schedContextName.3.106.111.101.4.49.51.116.104 = "engine1"
schedVariable.3.106.111.101.4.49.51.116.104 =
   smLaunchStart.3.106.111.101.5.103.104.111.115.116
```

```
    schedType.3.106.111.101.4.49.51.116.104 = oneshot(3)
    schedAdminStatus.3.106.111.101.4.49.51.116.104 = enabled(2)
    schedStorageType.3.106.111.101.4.49.51.116.104 = nonVolatile(3)
    schedRowStatus.3.106.111.101.4.49.51.116.104 = active(1)
```

   All the remaining columns in the schedTable represent status
   information and are not shown here.

5.3. Turning an interface off during weekends

   This example assumes that a network interface should be taken down
   during weekends. The interface table (ifTable) of the IF-MIB
   [RFC2863] is assumed to exist in the context identified by an empty
   string and the index of the interface is ifIndex = 6.

   The scheduling entry which brings the interface down on every Friday
   evening at 20:30 (8:30 pm) is owned by schedOwner = "bob" and its
   name is schedName = "if-off". The instance identifier for the
   scheduling entry is therefore 3.98.111.98.6.105.102.45.111.102.102.

```
    schedWeekDay.3.98.111.98.6.105.102.45.111.102.102 = { friday }
    schedMonth.3.98.111.98.6.105.102.45.111.102.102 = {
          january, february, march, april, may, june,
          july, august, september, october, november, december
    }
    schedDay.3.98.111.98.6.105.102.45.111.102.102 = {
          d1, d2, d3, d4, d5, d6, d7, d8, d9, d10,
          d11, d12, d13, d14, d15, d16, d17, d18, d19, d20,
          d21, d22, d23, d24, d25, d26, d27, d28, d29, d30, d31
    }
    schedHour.3.98.111.98.6.105.102.45.111.102.102 = { h20 }
    schedMinute.3.98.111.98.6.105.102.45.111.102.102 = { m30 }
    schedValue.3.98.111.98.6.105.102.45.111.102.102 = down(2)
    schedContextName.3.98.111.98.6.105.102.45.111.102.102 = ""
    schedVariable.3.98.111.98.6.105.102.45.111.102.102 =
      ifAdminStatus.6

    schedType.3.98.111.98.6.105.102.45.111.102.102 = calendar(2)
    schedAdminStatus.3.98.111.98.6.105.102.45.111.102.102 = enabled(1)
    schedStorageType.3.98.111.98.6.105.102.45.111.102.102 =
      nonVolatile(3)
    schedRowStatus.3.98.111.98.6.105.102.45.111.102.102 = active(1)
```

   The scheduling entry which brings the interface up on every Monday
   morning at 5:30 is owned by schedOwner = "bob" and its name is
   schedName = "if-on". The instance identifier for the scheduling
   entry is therefore 3.98.111.98.5.105.102.45.111.110.

The entry in the schedTable which brings the interface up again on
every Monday morning at 5:30 looks as follows:

```
schedWeekDay.3.98.111.98.5.105.102.45.111.110 = { monday }
schedMonth.3.98.111.98.5.105.102.45.111.110 = {
        january, february, march, april, may, june,
        july, august, september, october, november, december
}
schedDay.3.98.111.98.5.105.102.45.111.110 = {
        d1, d2, d3, d4, d5, d6, d7, d8, d9, d10,
        d11, d12, d13, d14, d15, d16, d17, d18, d19, d20,
        d21, d22, d23, d24, d25, d26, d27, d28, d29, d30, d31
}
schedHour.3.98.111.98.5.105.102.45.111.110 = { h5 }
schedMinute.3.98.111.98.5.105.102.45.111.110 = { m30 }

schedValue.3.98.111.98.5.105.102.45.111.110 = up(1)
schedContextName.3.98.111.98.5.105.102.45.111.110 = ""
schedVariable.3.98.111.98.5.105.102.45.111.110 = ifAdminStatus.6

schedType.3.98.111.98.5.105.102.45.111.110 = calendar(2)
schedAdminStatus.3.98.111.98.5.105.102.45.111.110 = enabled(1)
schedStorageType.3.98.111.98.5.105.102.45.111.110 = nonVolatile(3)
schedRowStatus.3.98.111.98.5.105.102.45.111.110 = active(1)
```

A similar configuration could be used to control other schedules.
For example, one could change the "if-on" and "if-off" schedules to
enable and disable the periodic scheduler defined in the first
example.

6. Security Considerations

There are a number of management objects defined in this MIB that
have a MAX-ACCESS clause of read-write and/or read-create. Such
objects may be considered sensitive or vulnerable in some network
environments. The support for SET operations in a non-secure
environment without proper protection can have a negative effect on
network operations.

SNMPv1 by itself is not a secure environment. Even if the network
itself is secure (for example by using IPSec), even then, there is no
control as to who on the secure network is allowed to access and
GET/SET (read/change/create/delete) the objects in this MIB.

It is recommended that the implementers consider the security
features as provided by the SNMPv3 framework. Specifically, the use
of the User-based Security Model RFC 2574 [RFC2574] and the View-
based Access Control Model RFC 2575 [RFC2575] is recommended.

It is then a customer/user responsibility to ensure that the SNMP
entity giving access to an instance of this MIB, is properly
configured to give access to the objects only to those principals
(users) that have legitimate rights to indeed GET or SET
(change/create/delete) them.

Scheduled SNMP set operations must use the security credentials that
were present when the corresponding row in the scheduling entry was
created. An implementation must therefore record and maintain the
credentials for every scheduling entry.

An implementation must ensure that access control rules are applied
when doing the set operation. This is accomplished by calling the
isAccessAllowed abstract service interface defined in RFC 2571
[RFC2571]:

```
    statusInformation =               -- success or errorIndication
      isAccessAllowed(
      IN    securityModel             -- Security Model in use
      IN    securityName              -- principal who wants to access
      IN    securityLevel             -- Level of Security
      IN    viewType                  -- read, write, or notify view
      IN    contextName               -- context containing variableName
      IN    variableName              -- OID for the managed object
            )
```

The securityModel, securityName and securityLevel parameters are set
to the values that were recorded when the scheduling entry was
created. The viewType parameter must select the write view and the
contextName and variableName parameters are taken from the
schedContextName and schedVariableName values of the scheduling
entry.

This MIB limits scheduled actions to objects in the local MIB. This
avoids security problems with the delegation of access rights.
However, it might be possible for a user of this MIB to own some
schedules that might trigger far in the future. This can cause
security risks if the security administrator did not properly update
the access control lists when a user is withdrawn from an SNMP
engine. Therefore, entries in the schedTable SHOULD be cleaned up
whenever a user is removed from an SNMP engine.

To facilitate the provisioning of access control by a security
administrator using the View-Based Access Control Model (VACM)
defined in RFC 2575 [RFC2575] for tables in which multiple users may
need to independently create or modify entries, the initial index is
used as an "owner index". Such an initial index has a syntax of

SnmpAdminString, and can thus be trivially mapped to a securityName
or groupName as defined in VACM, in accordance with a security
policy.

All entries in related tables belonging to a particular user will
have the same value for this initial index. For a given user's
entries in a particular table, the object identifiers for the
information in these entries will have the same subidentifiers
(except for the "column" subidentifier) up to the end of the encoded
owner index. To configure VACM to permit access to this portion of
the table, one would create vacmViewTreeFamilyTable entries with the
value of vacmViewTreeFamilySubtree including the owner index portion,
and vacmViewTreeFamilyMask "wildcarding" the column subidentifier.
More elaborate configurations are possible.

7. Intellectual Property

The IETF takes no position regarding the validity or scope of any
intellectual property or other rights that might be claimed to
pertain to the implementation or use of the technology described in
this document or the extent to which any license under such rights
might or might not be available; neither does it represent that it
has made any effort to identify any such rights. Information on the
IETF's procedures with respect to rights in standards-track and
standards-related documentation can be found in BCP 11, RFC 2028.
Copies of claims of rights made available for publication and any
assurances of licenses to be made available, or the result of an
attempt made to obtain a general license or permission for the use of
such proprietary rights by implementors or users of this
specification can be obtained from the IETF Secretariat.

The IETF invites any interested party to bring to its attention any
copyrights, patents or patent applications, or other proprietary
rights which may cover technology that may be required to practice
this standard. Please address the information to the IETF Executive
Director.

8. Changes from RFC 2591

The following list documents major changes from the previous version
of this document, published as RFC 2591:

- Updated the SNMP Management Framework boilerplate and the
   references.

- Added revision clauses to the module identity macro.

- Clarified the behavior during time transitions.

- Clarified that schedInterval and schedCalendarGroup objects can be
  modified regardless of the current value of schedRowStatus,
  schedAdminStatus and schedOperStatus.

- Added some additional boilerplate text to the security
  considerations section.

- Clarified that implementations must re-calculate any pending
  action invocations when scheduling parameters are modified.

- Clarified that schedOperStatus must not be enabled while the
  schedRowStatus is not active.

- Clarified that schedRowStatus can not be changed as long as the
  schedOperStatus is enabled.

- Clarified that implementations can delegate the isAccessAllowed
  check by sending themself an SNMP Set message.

- Added the schedTriggers object which counts the total number of
  triggers.

- Added DEFVALs for schedContextName, schedVariable, and schedValue
  and updated the schedRowStatus description.

- Deprecated schedCompliance, schedGroup and created
  schedCompliance2 and schedGroup2 that take care of the new
  schedTriggers object.
